Problem 1:

1. Test if the arguments are integers
2. Test if there are less than 2 arguments or not
3. Test if either of the arguments are not tiny

Problem 2:

I think that I should test what happens if I put in 3 arguments. Since the specification didn't specify what happens if there were 3 arguments, it is optimal that the program outputs an error if 3 arguments were to be put in so that the user realizes that the program isn't intended to accept 3 arguments. If the program were to output something from 3 arguments, the user might be misled into thinking that putting in 3 arguments is part of the intended function of the program. This could lead to further complications.
